

Decidability of termination problems for sequential P systems with active membranes

Michal Kováč

Faculty of Mathematics, Physics and Informatics, Comenius University

Abstract. An universal variant of sequential P systems with active membranes is investigated and we show that existence of infinite computation is decidable. The standard construction of coverability tree is extended to provide an algorithm for detecting infinite loops. On the other hand, the existence of a halting computation is shown to be undecidable, as it can be reduced to reachability of register machines.

1 Introduction

Membrane systems (P systems) were introduced by Păun (see [1]) as distributed parallel computing devices inspired by the structure and functionality of cells. One of the objectives is to relax the condition of using the rules in a maximally parallel way in order to find more realistic P systems from a biological point of view. In sequential P systems, only one rewriting rule is used in each step of computation. Without priorities, they are equivalent to vector addition systems [2], hence not universal. However priorities, inhibitors and other modifications can increase the computation power. It seems that there is a link between universality and ability to zero-check [3]. But there are also variants, where universality can be achieved without checking for zero, i.e. if we allow membranes to be created unlimited number of times [2]. Such P systems are called active P systems. Contrary, if we place a limit on number of times a membrane is created, such active P system is still equivalent to vector addition systems.

In section 2 we will recall some basic notions from formal languages, multisets and graph theory. Then in section 3 we will introduce membrane structure, formally define membrane configuration and active P system, because standard definitions are not convenient for our formal proofs. Section 4 contains main theorems with proofs.

2 Preliminaries

Here we recall several notions from the classical theory of formal languages.

An **alphabet** is a finite nonempty set of symbols. Usually it is denoted by Σ . A **string** over an alphabet is a finite sequence of symbols from alphabet. We denote by Σ^* the set of all strings over an alphabet Σ . By $\Sigma^+ = \Sigma^* - \{\varepsilon\}$ we denote the set of all nonempty strings over Σ . A **language** over the alphabet Σ is any subset of Σ^* .

The number of occurrences of a given symbol $a \in \Sigma$ in the string $w \in \Sigma^*$ is denoted by $|w|_a$. $\Psi_\Sigma(w) = (|w|_{a_1}, |w|_{a_2}, \dots, |w|_{a_n})$ is called a Parikh vector associated with the string $w \in \Sigma^*$, where $\Sigma = \{a_1, a_2, \dots, a_n\}$. For a language $L \subseteq \Sigma^*$, $\Psi_\Sigma(L) = \{\Psi_\Sigma(w) | w \in L\}$ is the Parikh mapping associated with L . If FL is a family of languages, PsFL is denoted the family of Parikh images of languages in FL.

A multiset over a set Σ is a mapping $M : \Sigma \rightarrow \mathbb{N}$. We denote by $M(a)$, $a \in \Sigma$ the multiplicity of a in the multiset M . The **support** of a multiset M is the set $\text{supp}(M) = \{a \in \Sigma | M(a) \geq 1\}$. It is the set of items with at least one occurrence. A multiset is **empty** when its support is empty. A multiset M with finite support $\{a_1, a_2, \dots, a_n\}$ can be represented by the string $a_1^{M(a_1)} a_2^{M(a_2)} \dots a_n^{M(a_n)}$. We say that multiset M_1 is included in multiset M_2 if $\forall a \in \text{supp}(M_1) : M_1(a) \leq M_2(a)$. We denote it by $M_1 \subseteq M_2$. If $M_1 \subseteq M_2$, the **difference** of two multisets $M_2 - M_1$ is defined as a multiset where $\forall a \in \text{supp}(M_2) : (M_2 - M_1)(a) = \max(M_2(a) - M_1(a), 0)$. The **union** of two multisets $M_1 \cup M_2$ is a multiset where $\forall a \in \text{supp}(M_1) \cup \text{supp}(M_2) : (M_1 \cup M_2)(a) = M_1(a) + M_2(a)$. The product of multiset M with natural number $n \in \mathbb{N}$ is a multiset where $\forall a \in \text{supp}(M) : (n \cdot M)(a) = n \cdot M(a)$.

Next, we recall notions from graph theory.

A **rooted tree** is a tree, in which a particular node is distinguished from the others and called the root node. Let T be a rooted tree. We will denote its root node by r_T . Let d be a node of $T \setminus \{r_T\}$. The node adjacent to d on the only path from d to r_T is called a **parent node** of d and is denoted by $\text{parent}_T(d)$. We will denote the set of nodes of T by $V(T)$ and set of its edges by $E(T)$. Let T_1, T_2 be rooted trees. A bijection $f : V(T_1) \rightarrow V(T_2)$ is an **isomorphism** iff $\{(f(u), f(v)) | (u, v) \in E(V(T_1))\} = E(V(T_2))$ and $f(r_{T_1}) = r_{T_2}$.

3 Active P systems

The fundamental ingredient of a P system is the **membrane structure** (see [4]). It is a hierarchically arranged set of membranes, all contained in the **skin membrane**. Each membrane determines a compartment, also called region, which is the space delimited from above by it and from below by the membranes placed directly inside, if any exists. Clearly, the correspondence membrane – region is one-to-one, that is why we sometimes use interchangeably these terms. Membrane structure can be also viewed as a rooted tree with the skin membrane as the root node.

Let Σ be a set of objects. Recall that \mathbb{N}^Σ contains all multisets of objects from Σ . **Membrane configuration** is a tuple (T, l, c) , where:

- T is a rooted tree,
- $l \in \mathbb{N}^{V(T)}$ is a mapping that assigns for each node of T a number (label), where $l(r_T) = 1$, so the skin membrane is always labeled with 1,
- $c \in (\mathbb{N}^\Sigma)^{V(T)}$ is a mapping that assigns for each node of T a multiset of objects from Σ , so it represents the contents of the membrane.

Active P system is a tuple $(\Sigma, C_0, R_1, R_2, \dots, R_m)$, where:

- Σ is a set of objects,
- C_0 is initial membrane configuration,
- R_1, R_2, \dots, R_m are finite sets of rewriting rules associated with the labels $1, 2, \dots, m$ and can be of forms:
 - $u \rightarrow w$, where $u \in \Sigma^+$, $w \in (\Sigma \times \{\cdot, \uparrow, \downarrow_j\})^*$ and $1 \leq j \leq m$
 - $u \rightarrow w\delta$, where $u \in \Sigma^+$, $w \in (\Sigma \times \{\cdot, \uparrow, \downarrow_j\})^*$ and $1 \leq j \leq m$
 - $u \rightarrow [{}_j v]_j$, where $u \in \Sigma^+$, $v \in \Sigma^*$ and $1 \leq j \leq m$

Although rewriting rules are defined as strings, u, v and w represent multisets of objects from Σ . For the first two forms, each rewriting rule may specify for each objects on the right side, whether it stays in the current region (we will omit the symbol \cdot), moves through the membrane to the parent region (\uparrow) or to a specific child region (\downarrow_j , where j is a label of a membrane). We denote these transfers with an arrow immediately after the symbol. An example of such rule is the following: $abb \rightarrow ab \downarrow_2 c \uparrow c$. Symbol δ at the end of the rule means that after the application of the rule, the membrane is dissolved and its contents (objects, child membranes) are propagated to the parent membrane. Active P systems differs from classical (passive) P systems in ability to create new membranes by rules of the third form.

For active P system $(\Sigma, C_0, R_1, R_2, \dots, R_m)$, configuration $C = (T, l, c)$, membrane $d \in V(T)$ with label $j = l(d)$ the rule $r \in R_j$ is **applicable** iff:

- $r = u \rightarrow w$ and $u \subseteq c(d)$ and $\forall (a, \downarrow_k) \in w \exists d_2 \in V(T) : l(d_2) = k \wedge \text{parent}(d_2) = d$,
- $r = u \rightarrow w\delta$ and $u \subseteq c(d)$ and $\forall (a, \downarrow_k) \in w \exists d_2 \in V(T) : l(d_2) = k \wedge \text{parent}(d_2) = d$ and $d \neq r_T$,
- $r = u \rightarrow [{}_k v]_k$ and $u \subseteq c(d)$

Active P system with a limit on total number of membranes is a tuple $(\Sigma, L, C_0, R_1, R_2, \dots, R_m)$, where $(\Sigma, C_0, R_1, R_2, \dots, R_m)$ is an active P system and $L \in \mathbb{N}$ is a limit on total number of membranes. Anytime during the computation, a configuration (T, l, c) is not allowed to have more than L membranes, so the following invariant holds: $|V(T)| \leq L$.

This is achieved by adding a constraint for rule of the form $r = u \rightarrow [{}_k v]_k$, which is defined to be applicable iff $u \subseteq c(d)$ and $|V(T)| < L$. If the number of membranes is equal to L , there is no space for newly created membrane, so in that case such rule is not applicable.

A **computation step** of P system is a relation \Rightarrow on the set of configurations such that $C_1 \Rightarrow C_2$ holds iff there is an applicable rule in a membrane in C_1 such that applying that rule would result in C_2 .

An **infinite computation** of a P system is an infinite sequence of configurations $\{C_i\}_{i=0}^\infty$, where $\forall i : C_i \Rightarrow C_{i+1}$.

A **finite computation** of a P system is a finite sequence of configurations $\{C_i\}_{i=0}^n$, where $\forall i : C_i \Rightarrow C_{i+1}$.

A **halting computation** of a P systems is a finite computation $\{C_i\}_{i=0}^n$, where there is no applicable rule in the last configuration C_n .

There are two possible ways of assigning a result of a computation:

1. By considering the multiplicity of objects present in a designated membrane in a halting configuration. In this case we obtain a vector of natural numbers. We can also represent this vector as a multiset of objects or as Parikh image of a language.
2. By concatenating the symbols which leave the system, in the order they are sent out of the skin membrane (if several symbols are expelled at the same time, then any ordering of them is considered). In this case we generate a language.

The result of a single computation is clearly only one multiset or a string, but for one initial configuration there can be multiple possible computations. It follows from the fact that there can be more than one applicable rule in each configuration.

3.1 Register machines

As a referential universal language acceptor we will use Minsky's register machine. Such a machine runs a program consisting of numbered instructions of several simple types.

Definition 1. *A n -register machine is a tuple $M = (n, P, i, h)$, where:*

- n is the number of registers,
- P is a set of labeled instructions of the form $j : (op(r), k, l)$, where $op(r)$ is an operation on register r of M , and j, k, l are labels from the set $Lab(M)$ (which numbers the instructions in a one-to-one manner),
- i is the initial label, and
- h is the final label.

The machine is capable of the following instructions:

- $(add(r), k, l)$: Add one to the contents of register r and proceed to instruction k or to instruction l ; in the deterministic variants usually considered in the literature we demand $k = l$.
- $(sub(r), k, l)$: If register r is not empty, then subtract one from its contents and go to instruction k , otherwise proceed to instruction l .
- $halt$: This instruction stops the machine. This additional instruction can only be assigned to the final label h .

A deterministic m -register machine can analyze an input $(n_1, \dots, n_m) \in \mathbb{N}^m$ in registers 1 to m , which is recognized if the register machine finally stops by the halt instruction with all its registers being empty (this last requirement is not necessary). If the machine does not halt, the analysis was not successful.

4 Termination problems

In this section we recall the halting problem for Turing machines. The problem is to determine, given a deterministic Turing machine and an input, whether the Turing machine running on that input will halt. It is one of the first known undecidable problems. On the other hand, for non-deterministic machines, there are two possible meanings for halting. We could be interested either in:

- whether there exists an infinite computation (the machine can run forever),
or
- whether there exists a finite computation (the machine can halt)

We will prove the (un)decidability of these problems on active P systems with limit on total number of membranes. The results are quite interesting, because:

Theorem 1. *Sequential active P systems with limit on total number of membranes are universal.*

Proof. The proof of this theorem for sequential active P systems in [2] uses simulation of register machines and during the simulation, every configuration has at most three membranes, hence the universality holds also for sequential active P systems with limit on total number of membranes. \square

4.1 Existence of infinite computation

We will propose an algorithm for deciding existence of infinite computation. Basic idea is to consider the minimal coverability graph ([5]), where nodes are configurations and edge leads from the configuration C_1 to the configuration C_2 , whenever there is a rule applicable in C_1 , which results in C_2 . The construction in [5] is performed on Petri nets, where the configuration consists just of a vector of natural numbers. The situation is the same for single-membrane sequential P systems. We need to modify the construction for active P systems.

A configuration $C_2 = (T_2, l_2, c_2)$ **covers** configuration $C_1 = (T_1, l_1, c_1)$ iff \exists isomorphism $f : T_1 \rightarrow T_2$ preserving membrane labels and contents: $\forall d \in T_1$ the following properties hold: $l_1(d) = l_2(f(d)) \wedge c_1(d) \subseteq c_2(f(d))$.

We will denote this with $C_1 \leq C_2$.

Lemma 1. *For sequential active P system with limit on total number of membranes, if $C_2 = (T_2, l_2, c_2)$ **covers** configuration $C_1 = (T_1, l_1, c_1)$, then there is an isomorphism $f : T_1 \rightarrow T_2$ such that if a rule r is applicable in membrane $d \in T_1$, then r is applicable in $f(d)$.*

Proof. Suppose r is applicable in d . Then the left side u of the rule r is contained within the contents of the membrane $u \subseteq c_1(d)$. Because $C_1 \leq C_2$, then there is an isomorphism $f : T_1 \rightarrow T_2$ such that $c_1(d) \subseteq c_2(f(d))$ and then $u \subseteq c_2(f(d))$.

There are three possible forms of the rule r .

- If $r = u \rightarrow w$, then because r is applicable in d , $\forall(a, \downarrow_k) \in w \exists d_2 \in V(T_1) : l_1(d_2) = k \wedge \text{parent}_{T_1}(d_2) = d$. Because $C_1 \leq C_2$, then for $f(d_2) \in V(T_2)$ the following holds: $l_2(f(d_2)) = l_1(d_2) = k$ and $\text{parent}_{T_2}(f(d_2)) = f(d)$. Hence r is applicable in $f(d)$.
- If $r = u \rightarrow w\delta$, then $d \neq r_{T_1}$. Since f is an isomorphism, then also $f(d) \neq r_{T_2}$. Other properties follows from the previous case.
- If $r = u \rightarrow [{}_kv]_k$, then $|V(T_1)| < L$. Isomorphism preserves number of nodes, hence $|V(T_2)| = |V(T_1)| < L$ and r is applicable in $f(d)$. \square

Now, we will define the encoding of a configuration $C = (T, l, c)$ into a tuple of integers.

A membrane $d \in T$ will be encoded as $(n + m)$ -tuple $\text{enc}(d) \in \mathbb{N}^{(n+m)}$, where first n numbers will be actual counts of objects: $\text{enc}(d)_i = c(d)(a_i)$ for $i \leq n$. Next m numbers will encode the membrane label: $\text{enc}(d)_{n+j} = 0$ for $l(d) \neq j \leq m$ and $\text{enc}(d)_{n+l(d)} = 1$.

The entire tree will be encoded into concatenated sequences of encoded nodes in the preorder traversal order. This sequence is then padded with zeroes to have length $(n + m)L$ as that is the maximal length of encoded tree.

Example 1. Suppose skin membrane with label 1 and contents $a_1^2 a_2$ with a child membrane with label 2 and contents a_2^2 . Then the encoding will be 21100201

Since there are only finitely many non-isomorphic trees with at most L nodes ([6]), there is a constant z such that we can uniquely assign the tree an order number $o(T) \leq z$.

The entire configuration will be encoded in tuple which consists of z parts. All but the part with index $o(T)$ will contain just zeros. The part with index $o(T)$ will contain the encoding of the tree.

Lemma 2. For configurations $C_1 = (T_1, l_1, c_1)$ and $C_2 = (T_2, l_2, c_2)$, $\text{enc}(C_1) \leq \text{enc}(C_2) \Rightarrow C_1 \leq C_2$.

Proof. If the $\text{enc}(C_1) \leq \text{enc}(C_2)$, then $o(T_1) = o(T_2)$, so the trees are isomorphic. For every membrane $d \in T_1$, $l_1(d) = l_2(f(d))$ and $c_1(d) \subseteq c_2(f(d))$. Hence, $C_1 \leq C_2$. \square

Lemma 3. For sequential active P system with limit on total number of membranes L for every infinite sequence of configurations $\{C_i\}_{i=0}^\infty \exists i < j : C_i \leq C_j$.

Proof. Suppose an infinite sequence $\{\text{enc}(C_i)\}_{i=0}^\infty$. We use a variation of Dickson's lemma ([7]): Every infinite sequence of tuples from \mathbb{N}^k contains an increasing pair. Applied to our sequence, there are two positions $i < j : \text{enc}(C_i) \leq \text{enc}(C_j)$. From lemma 2, $C_i \leq C_j$. \square

Theorem 2. Existence of infinite computation for active P systems with limit on total number of membranes is decidable.

Proof. Algorithm for deciding the problem will traverse the reachability graph. When it encounters a configuration that covers another configuration, from lemma 1 follows that the same rules can be applied repeatedly, so the algorithm will halt with the answer YES. Otherwise, the algorithm will answer NO. Algorithm will always halt, because if there was an infinite computation, from lemma 3 there would be two increasing configurations which is already covered in the YES case. \square

4.2 Existence of halting computation

We will reduce the problem of deciding existence of halting computation to the problem of reachability of a given configuration. For a given P system Π and a target configuration C we will construct a P system Π' such that there is a halting computation of Π' iff the Π can reach configuration C . Suppose $\Pi = (\Sigma, C_0, R_1, \dots, R_m)$ and $C = (T, l, c)$. Then $\Pi' = (\Sigma', C'_0, R'_1, \dots, R'_m)$, where:

- $\Sigma' = \Sigma \cup \{\omega, \sigma\} \cup \{\xi_d | d \in V(T)\}$,
- $C'_0 = (T, l, c')$, where $\forall d \in V(T) \setminus r_T : c'(d) = c(d) \cup \{\omega\}$ and $c'(r_T) = c(r_T) \cup \{\omega \xi_{r_T}\}$,
- $\forall i \in \{1 \dots m\} : R'_i = \{r | r \in R_i, r = u \rightarrow w \vee r = u \rightarrow w\delta\} \cup \{u \rightarrow [{}_k v \omega]_k | u \rightarrow [{}_k v]_k \in R_i\} \cup \{a \rightarrow a | a \in \Sigma\} \cup \{\sigma\sigma \rightarrow \sigma\sigma, \omega \rightarrow \omega\} \cup \{\xi_d \omega c(d) \rightarrow \sigma \xi_{d'} \downarrow_{l(d')} | d, d' \in V(T), l(d) = i, \text{parent}(d') = d\}$

At the start, every membrane contains an additional ω and a rule $\omega \rightarrow \omega$, so the computation will halt only if these ω s are erased. The ξ_{r_T} object is called verifier, it verifies if the contents of each membrane corresponds to the contents in the target configuration C . After this verification it descends down into child membranes for the verification of other parts of the membrane structure. It also replaces ω with σ , which stands as a trace symbol, meaning that the contents of this membrane has already been verified. σ objects are used to eliminate dissolution of membranes when ξ object has already verified the contents. Such dissolution would cause to two σ s to meet in the same membrane which would cause an infinite computation.

Lemma 4. *If C is reachable for Π then there is a halting computation of Π' .*

Proof. Consider computation Π with C as the last configuration. The corresponding computation of Π' will result in a configuration, where in every membrane d , the contents will be $\omega c(d)$, and the skin membrane will contain an additional ξ_{r_T} . Then the cascade of applications of rule $\xi_d \omega c(d) \rightarrow \sigma \xi_{d'} \downarrow_{l(d')}$ can be applied, starting in the skin membrane and cascading down to children until all the membranes applied that rule. The objects $\omega c(d)$ will be replaced by σ and the computation will halt. \square

The other direction of the theorem 3 is more complicated, so the proof is split into several lemmas.

Lemma 5. *For all halting computations of Π' there is no rule of form $u \rightarrow w\delta$ applied in the membrane d' after the application of rule $\xi_d\omega c(d) \rightarrow \sigma\xi_{d'} \downarrow_{l(d')}$ in membrane $d = \text{parent}(d')$.*

Proof. After the application of rule $\xi_d\omega c(d) \rightarrow \sigma\xi_{d'} \downarrow_{l(d')}$, the object σ remains in the membrane. There is no interaction of σ with other objects, only with another σ . If a child membrane d' is dissolved with a rule $u \rightarrow w\delta$, then two symbols σ will meet in the membrane d and the computation will not halt, which contradicts the fact that the computation is halting. \square

Lemma 6. *For all halting computations of Π' there is no rule of form $u \rightarrow [\kappa v\omega]_k$ applied in the membrane d' after the application of rule $\xi_d\omega c(d) \rightarrow \sigma\xi_{d'} \downarrow_{l(d')}$.*

Proof. After the application of rule $r = \xi_d\omega c(d) \rightarrow \sigma\xi_{d'} \downarrow_{l(d')}$ in membrane d , there won't be any of ξ symbols present in the membrane, because they are only sent into child membranes, which cannot be dissolved because of lemma 5. So there will be no more of rule r applied in membrane d . The newly created membrane will never receive any of ξ objects, so the object ω will never be erased and the computation will not halt, which contradicts the fact that the computation is halting. \square

Lemma 7. *For all halting computations of Π' there is a halting computation, where for every membrane d the last rule used is $r = \xi_d\omega c(d) \rightarrow \sigma\xi_{d'} \downarrow_{l(d')}$.*

Proof. Consider membrane d : let C_1 be the configuration before the application of r , C_2 the configuration after the application of r and C_3 the halting configuration. The sequence of steps from C_2 to C_3 cannot use σ , so the same sequence can be applied starting from C_1 instead of C_2 . It would result in a configuration C_4 , where contents of d is exactly $\xi_d\omega c(d)$. So the rule $r = \xi_d\omega c(d) \rightarrow \sigma\xi_{d'} \downarrow_{l(d')}$ can be applied, resulting in configuration, where d contains exactly one σ and nothing else, so no more rule will be applied in d . \square

Lemma 8. *If there is a halting computation of Π' then C is reachable for Π .*

Proof. According to lemma 7 there is also a halting computation C_4 where in every membrane d the last used rule is $r = \xi_d\omega c(d) \rightarrow \sigma\xi_{d'} \downarrow_{l(d')}$. So the corresponding computation in Π will result in the configuration C_5 , where every membrane d contains exactly $c(d)$. If C_5 contains a membrane not present in C , it will contain the object ω , which won't be reached by any of objects ξ so the computation will not halt. If C contains a membrane d' not present in C_5 , then in $d = \text{parent}(d')$ at C_5 still contains ω because the rule $r = \xi_d\omega c(d) \rightarrow \sigma\xi_{d'} \downarrow_{l(d')}$ could not be applied due to lack of a child membrane d' . Hence $C = C_5$ and there is a computation of Π that will result in C . \square

Theorem 3. *Existence of halting computation for active P systems with limit on total number of membranes is undecidable.*

Proof. For a given P system Π and a target configuration C we have constructed a P system Π' such that there is a halting computation of Π' iff the Π can reach configuration C . The two directions of the equivalence have been proven in lemmas 4 and 8. Using this construction, we can reduce the existence of halting computation to reachability of register machines [2], which is known to be undecidable. \square

5 Conclusion

We have studied the termination problems for active sequential P systems. Unlike deterministic systems, the termination problems cannot be simply reduced to the halting problem. We have shown that active P systems with limit on number of membranes have decidable existence of infinite computation and undecidable existence of halting computation. It is currently unknown whether the same results apply also for a variant without the limit on the number of membranes, so it could be a subject for the future study.

Regarding the open problem stated in [2] about sequential active P systems with hard membranes (without communication between membranes), it could be interesting to find a connection between the universality and decidability of these termination problems.
